Spinal cord hemangioblastoma

Usually non-infiltrating, well demarcated, may have cystic caps. 33% of patients with spinal hemangioblastoma will have Von Hippel Lindau disease. Cannot incise nor core because of vascularity. Requires microsurgical approach similar to AVM, possibly with intraoperative hypotension.

Epidemiology

see Spinal cord hemangioblastoma epidemiology.

Clinical Features

Clinical presentation is similar to that of other spinal cord tumors, with pain, weakness and sensory changes common. Rarely, spinal hemangioblastomas may cause subarachnoid haemorrhage or hematomyelia.

Pathology

Haemangioblastomas are vascular benign (WHO grade I) lesions and they do not undergo malignant degeneration.

Histologically, they consist of large pale stromal cells packed between blood vessels.

Radiographic features

The most common location is the thoracic cord (50%), followed by the cervical cord (40%).

The majority of haemangioblastomas have an intramedullary component with two thirds located eccentrically and having an exophytic component (most commonly along the dorsum of the cord 8). Only 25% percent are entirely intramedullary. A minority appear entirely extramedullary and only rarely are they extradural.

Eighty percent of haemangioblastomas are solitary. If multiple lesions are present, Von Hippel-Lindau syndrome should be suspected.

The prevalence of syringomyelia due to SH is considerably high, and the initial clinical presentation of syringomyelia resulting from SH should be emphasized 1).

Angiography

A densely enhancing nidus with associated dilated arteries and prominent draining veins is characteristic for a hemangioblastoma.
CT

On non-contrast CT they may be seen as a soft tissue nodule often with a prominent hypodense cyst-like component. Contrast administration results in vivid enhancement of the solid component.

MRI

Although they usually appear as discrete nodules, there can be diffuse cord expansion. An associated tumour cyst or syrinx is common (50-100%) 2,4. Additionally they may rarely be a source of subarachnoid haemorrhage or haematomyelia.

Reported signal characteristics of the solid components include:

T1: variable relative to normal spinal cord.
  hypo-isointense most common, and difficult to identify
  hyperintense (25%)

T2
  iso-hyperintense
  focal flow voids especially in larger lesions
  surrounding oedema and associated syrinx are usually seen
  hemosiderin capping may be present

T1 C+ (Gd): the tumour nodule enhances vividly

Care should be taken to image the whole neuraxis to ensure that no other lesions are present.

Differential diagnosis

The differential diagnosis can be though of in two groups on account of the main features of these tumours: neoplasms of the spinal canal (enhancing component) and vascular malformations of the spinal cord (enlarged vessels)

Other enhancing masses to be considered include:

intradural extramedullary tumours
spinal meningioma
myxopapillary ependymoma
leptomeningeal spinal metastases
neurogenic tumours
spinal schwannoma
spinal neurofibroma
spinal paraganglioma
intramedullary spinal cord tumours
spinal cord metastases
spinal astrocytoma
spinal ependymoma
Vascular malformation to consider include:
other hypervascular cord neoplasms
spinal arteriovenous malformation
spinal dural arteriovenous fistula
spinal cavernous malformations

**Treatment**

Spinal cord hemangioblastoma treatment.

**Outcome**

Hemangioblastomas are slow growing.

**Case series**

Spinal cord hemangioblastoma case series.

**Case reports**

As vascular tumors, intramedullary hemangioblastomas are associated with significant intraoperative blood loss, making them particularly challenging clinical entities. The use of intraoperative indocyanine green or other fluorescent dyes has previously been described to avoid breaching the tumor capsule, but improved surgical outcomes may result from identifying and ligating the feeder arteries and arterIALIZED draining veins.

To describe the use of combined preoperative angiography and intraoperative indocyanine green use for the identification of feeder arteries and arterialized draining veins to decrease blood loss in the resection of intramedullary hemangioblastomas.
A patient with cervical myelopathy secondary to a large C3 hemangioblastoma and cervicothoracic syrinx underwent a C2-3 laminoplasty with resection of the lesion. To reduce intraoperative blood loss and facilitate safe lesion resection, the vascular architecture of the lesion was defined via preoperative digital subtraction angiography and intraoperative use of indocyanine green. The latter permitted ligation of the major and minor feeding arteries and arterialized veins prior to tumor breach, allowing for facile en bloc resection of the lesion.

The lesion was resected en bloc with minimal blood loss (approximately 100 mL) and without intraoperative neuromonitoring signal changes. The patient remained at neurological baseline throughout their stay.

Molina et al., presented a written and media illustration of a technique for intraoperative indocyanine green use in the en bloc resection of intramedullary hemangioblastoma 2).
